There is scarcely a person alive today who has not seen or felt the impact of Alzheimer’s disease (AD). AD ranks sixth among the leading causes of death in the United States. By disrupting memories, cognition, personality, and more, AD is extremely stressful for family members, friends and caregivers. Alzheimer’s disease will claim a greater toll as our population ages—unless something more is done.

With generous donor support, the Alzheimer’s Disease Research (ADR) program, which began in 1985, has funded nearly $140 million in research to understand and cure this disease. With our grants, scientists around the world have developed and tested thousands of hypotheses about how the disease destroys brain function over time. As part of this, they are investigating hundreds of ideas to diagnose, treat and cure dementia.

This yearbook provides an overview of BrightFocus’ current ADR grant projects. BrightFocus Foundation does not direct funding to specific techniques or categories of research. Applications from scientists for funding can be on any aspect of understanding and curing dementia. Each year, the proposals are evaluated by a Scientific Review Committee (SRC) made up of expert scientists from around the world. Our SRC recommends projects that are the most cutting-edge and innovative. The generosity of our donors helps make this possible.

The current portfolio of 132 ADR grants is expansive. In this yearbook, our active projects have been arranged in categories according to the Common Alzheimer’s Disease Research Ontology classification system, which is used by research funding agencies around the world, and also used by national and international authorities to track progress towards meeting Alzheimer’s research goals.

The scientific images at right were furnished by current ADR grantees and show various aspects of their work. Look inside for more information, including a brief description of what’s depicted in each image along with the grantee and lab that provided it.

Co-principal investigator and fellowship mentor institutions are listed if different than the PI.
There are many versions of amyloid protein in the human body, and most serve a useful role. Amyloid beta (Aβ) is a type of amyloid that is prone to molecular changes that create fragments that accumulate in the brain. A healthy brain is able to break down Aβ and eliminate it, but in Alzheimer’s disease (AD), Aβ forms hard, insoluble plaques that are toxic to neurons and are sometimes (not always) associated with AD-related memory loss and other changes. Once only seen after autopsy, new technologies have made it possible to measure Aβ plaques and learn which parts of the brain are most affected. Anti-amyloid drugs are being tested in clinical trials, with the hope of preventing formation of Aβ plaques in the future.

The Effect of the TTR Protein on Alzheimer’s Disease

Our goal is to answer conclusively whether transthyretin (over)expression in a post-developmental setting is an effective approach to either prevent or change the course of disease progression in Alzheimer’s and assess the potential of AAV gene therapy approach for translation into human clinical trials.

www.brightfocus.org/grant/A2019468F
Nanobodies Stabilizing Fragile Molecular Machines to Lower the Production of Toxic Amyloid-B in Alzheimer’s Disease

The molecular machinery that produces harmful material (amyloid beta) in the brain of people affected with Alzheimer’s disease is well known. Our research has recently shown that this molecular machinery (called gamma-secretase) is fragile and prone to malfunctioning, but fortunately the use of ‘stabilizing’ molecular bricks can stop its malfunction and prevent the production of toxic, Alzheimer’s-causing material. In this project we will generate novel stabilizing nanobricks (called nanobodies) to stabilize gamma-secretase and thus prevent the production of toxic amyloid beta. The novel nanobody stabilizers could pave the way for Alzheimer’s therapy.

How Autophagy Recognizes & Degrades Alzheimer’s Disease-Causing Amyloids in the Brain

The goal is to understand how autophagy, a protein degradation pathway, regulates Aβ metabolism and prevents neuronal inflammation in the Alzheimer’s brain.

www.brightfocus.org/grant/A2018100S

A New Method to Determine Alzheimer’s and Parkinson’s Toxins in the Lipid-Riched Environment

In diseases such as Alzheimer’s and Parkinson’s, toxic proteins accumulate and form holes in the nerve cells. Accumulated proteins are dynamic and take on different conformational shapes, making it difficult to study the features and functions of the protein. These proteins can be stabilized with experimental protein/lipid scaffolds in order to determine their structure with x-ray analysis. Understanding the structure of these accumulated toxic proteins will give insight into mechanisms of toxicity.

Understanding the Function of the Biomolecule Polyphosphate During Aging and Alzheimer’s Disease  
The highly-conserved polymer polyphosphate was recently found to protect cells and organisms from the toxic effects of amyloidogenic proteins, such as amyloid beta. The goal of this project is to characterize how polyphosphate changes with age, modifies amyloid beta toxicity, and influences susceptibility to Alzheimer’s disease.

**Relationship Between Biological Clock and γ-Secretase, the Enzyme Responsible for Generating Senile Plaques in Alzheimer’s Disease**  

Although the cause of Alzheimer’s disease (AD) is poorly understood, the disease progression is associated with amyloid beta peptide senile plaques and sleeping disorder, suggesting malfunction in internal biological clock and alteration of circadian rhythm. Interestingly, our initial data discovered that γ-secretase activity, the enzyme responsible for Aβ plaques generation, also exhibits a daily circadian oscillation. This project will reveal the molecular interaction between circadian function, γ-secretase activity and the connection to AD.

**Fingerprinting In Vivo and In Vitro Prion Strains**  

Alzheimer’s Disease (AD) is associated with the misfolding of tau and Aβ proteins. AD shares important molecular characteristics with classical PrP prion diseases, including the induced misfolding of soluble proteins in an autocatalytic manner and the accumulation of insoluble amyloids. Different conformational strains of PrP give rise to different neurodegenerative diseases. Conformation sensitive dyes are used to rapidly screen and fingerprint these conformational strains of prion proteins.

**A New Method to Separate Sub-groups of Alzheimer’s Disease by Measuring sAPPβ in Human Cerebrospinal Fluid**  

The goal of this project is to measure how quickly an Alzheimer’s patient’s brain makes a protein known as sAPPβ, and compare this to a healthy patient’s brain, to determine if in Alzheimer’s disease (AD) there is more sAPPβ being made than normal. Also, there is increasing evidence that not every patient’s AD has the same cause. So additionally, we want to use sAPPβ and other proteins such as sAPPα and Aβ, to determine if there are subgroups within AD patients that might respond in different ways to drugs that target AD.  

[www.brightfocus.org/grant/A2019520S](http://www.brightfocus.org/grant/A2019520S)
Biology of Fats and Proteins (APOE)

Initially recognized for its role in cardiovascular disease, the APOE gene also plays a role in Alzheimer’s disease. Its primary function is to regulate a class of proteins involved in the metabolism of fats (lipids) in the body. However, APOE has several common variants (or “alleles”) whose effects vary. The e4 allele, in particular, is the most prevalent genetic factor associated with late-onset Alzheimer’s disease, and may cause an increased risk and/or earlier onset. Its impact varies depending on whether the mutation appears on one or both chromosomes, as well as a person’s race and ethnicity (i.e., risk is not increased uniformly across all ethnic groups). Scientists are still trying to find out the reasons why. Some clues may lie with APOE’s interactions with the immune system, where it influences inflammation and a type of cellular damage known as oxidation. Also, while the APOE gene influences the breakdown of amyloid beta protein located in and around neurons, its e4 variant is less effective at doing so.

**The Role of Signaling Factors that Modulate Immune and Metabolic Function In Alzheimer’s Disease**

Irreversible loss of brain cells and brain function may already exist by the time patients start developing memory loss due to Alzheimer’s disease. Therefore, it is imperative to identify the earliest changes occurring in Alzheimer’s disease, as they may yield new ways to intervene before irreversible brain damage has occurred. During the very early stages of Alzheimer’s disease, when the memory remains relatively intact, there are significant changes in immune and metabolic function that contribute to Alzheimer’s disease; however, the underlying cause of these changes remains unclear. The goal of this project is to identify the circulating factors that affect immune and metabolic function early in Alzheimer’s disease before the memory loss and determine how they are involved in the overall disease process.

**Explore the Impacts of APOE Genotype Switching from APOE4 To APOE2 in the Periphery (Liver and Bloodstream) for Alzheimer’s Disease Therapy**

Having apolipoprotein E4 (APOE4) gene increases a person’s risk, whereas having APOE2 is protective for Alzheimer’s disease (AD). Our previous study found that ApoE4 produced in the liver compromises the vascular heath and impairs brain function (even though ApoE4 circulating in the bloodstream does not get into the brain). Using our unique mouse model in which ApoE2 is produced in the liver of ApoE4 mice, our studies will for the first time test whether converting harmful ApoE4 to protective ApoE2 in the liver can restore brain functions. In addition, this study will examine whether treating ApoE4 mice with ApoE2 young blood promotes aging-related memory deficits and reduces AD progression. Our findings will provide preclinical evidence for designing future human clinical trials, which may offer individualized treatment strategies based on APOE genotype.

**Assessment of Associations Between ApoE4 in the Blood, Behavior and Alzheimer’s Disease Related Changes Inside the Brain**

Alzheimer’s is a disease of the brain for which the risk is partially determined by a heritable factor, APOE4. This project will investigate the potential effects of a specific APOE4-linked liver-generated blood profile on disease-related changes inside the brain. A successful discovery of a factor that can be targeted in the periphery, rather than in the brain, for the cure or prevention of AD would facilitate the development of medication to prevent the disease.

**A New Approach to Treating Tauopathy by Lowering Apolipoprotein E Level**

The researchers will determine if decreasing apolipoprotein E (ApoE) levels in the brain can alter tau aggregation and tau-induced neurodegeneration, and we will also try to determine how ApoE exerts its effects on tau.

[www.brightfocus.org/grant/A2018128F](http://www.brightfocus.org/grant/A2018128F)

5.8 million people live with Alzheimer’s in the United States today and by 2050 there will be close to 15 million.
Biomarkers

Biomarkers are early markers of biological changes associated with Alzheimer’s disease (AD), which may begin causing gradual changes in the brain some 10-20 years before the onset of symptoms. The best hope of stopping AD is during this phase, and the need for earlier treatment makes the search for biomarkers critically important. Numerous types of biomarkers are in development, including tests to measure elevated amyloid beta (Aβ) levels in blood and/or cerebrospinal fluid; use of advanced imaging to detect tiny changes in brain structure; and techniques identifying Aβ protein deposits in the retina of the eye that mirror those in the brain. Biomarkers like these can help identify who is most likely to develop AD in the future, and what type, and also provide reliable measures of disease progress. This will help guide treatment decisions in the future, when drugs become available, determining such things as who needs treatment, when to start, and which drugs and treatment strategies are most likely to be successful.

Using Naturalistic Driving Behavior to Identify Older Adults with Preclinical or Symptomatic Alzheimer’s Disease

Crashes are a leading cause of injury and deaths among older adults, with as many as 19 older adults killed each day, and crashes are higher among persons with Alzheimer disease (AD). Since 2015, we tested a new way to continuously collect driving behaviors (distances, speeding, hard braking, times of day driving, etc) by plugging a device into people’s cars and recording how they drive. This was termed the “Driving Real-World In-Vehicle Evaluation System” (DRIVES). We will use the DRIVES technology to see if we can sort out those who have early AD from those who do not. We will also look at whether or not other tests of brain abilities, including navigation (finding one’s way around), physical functioning, and sensory functioning (vision, hearing, smell), can help pinpoint individuals with early AD more accurately.

Investigating Neuropeptides as Biomarkers and Novel Therapeutics for Alzheimer’s Disease

Alzheimer’s disease (AD) is currently defined by the abundance of two insoluble proteins, amyloid beta (Aβ) and tau, but the amount of these proteins does not accurately predict cognitive problems in people with AD. Recent studies have found that neuropeptides are widely dysregulated in AD, and might play roles in the AD disease process. In this proposal, we investigate whether neuropeptides may be used to more accurately assess AD patients, and whether supplementation with these peptides might eventually prove a new potential therapy for AD.

Rapid Assessment of Cognition Using Smartphones to Track Early Changes in Alzheimer’s Disease

One of the biggest challenges we face in Alzheimer’s disease research and clinical trials is tracking the subtle cognitive changes that appear years before a clinical diagnosis. Standard cognitive tests were not designed for this purpose and thus have poor sensitivity and poor reliability. This study will adapt cognitive measures for rapid and repeatable administration on participant’s personal smartphones with the goal of producing highly reliable assessments.

www.brightfocus.org/grant/A2018202S

Unraveling the Biological Overlap of Alzheimer’s Disease and Dementia with Lewy Bodies

Dementia with Lewy bodies (DLB) is a disabling disease that is difficult to diagnose because it often looks similar to Alzheimer’s disease (AD). Our research aims to uncover key differences between these two disorders by using cutting edge techniques to analyze protein levels in the brain and its surrounding fluid. Unraveling the biological overlap between these two dementias could help make DLB easier to recognize and effectively treat.

www.brightfocus.org/grant/A20201577F

A Novel Non-Invasive MRI-Based Biomarker of Early Stages of Alzheimer’s Disease

Develop and validate multimodality MRI techniques, a collection of individual techniques which, when they are added together, can help to detect and quantify Alzheimer’s progression, even when it occurs without behavioral symptoms.

www.brightfocus.org/grant/A2016251S
A Simple Blood Test to Identify Individuals at Risk of Developing Alzheimer’s Disease

Presently, there is no simple way to diagnose Alzheimer’s disease (AD) or to identify individuals likely to develop the disease in the future: current tests require expensive brain imaging or inconvenient puncture of the spine. To address these challenges, we have developed a high-performance blood test that measures a specific disease-related change (called phosphorylation) on a key Alzheimer-associated protein called tau. Initial clinical applications have shown that the new test accurately identifies AD patients and at-risk individuals from healthy patients, and provides important insights into memory decline and brain shrinkage (both key processes associated with the disease) one year ahead of a typical clinical diagnosis. In this study, we propose to investigate, in three uniquely large patient cohorts recruited across three continents and closely monitored for up to a decade, whether our new blood test can predict with high accuracy who is likely to develop AD several years ahead of diagnosis by standard methods, in order to support early treatment, clinical management and recruitment for therapy trials.

www.brightfocus.org/grant/A2020812F

Optical Coherence Tomography Angiography Based Assessment of Retinal Capillary Density as a Biomarker of Vascular Cognitive Impairment and Dementia

Vascular contributions to cognitive impairment and dementia (VCID) arise from stroke and other vascular brain injuries that cause significant changes to memory, thinking, and behavior. VCID often occurs in and contributes to Alzheimer’s Disease dementia. The damage in the small blood vessels is very difficult to detect with conventional testing or brain imaging methods like Magnetic Resonance Imaging (MRI). The goal of Dr. Kashani’s research is to develop new methods using the eye to detect the onset, progression and severity of VCID.

www.brightfocus.org/grant/CA2020004

This proposal is funded through a partnership between the Brightfocus Foundation and the National Institute of Neurological Disorders and Stroke (NINDS) (as NINDS supplement 3UH3NS100614-04S1). BrightFocus is supporting this study as a part of the NINDS MarkVCID Consortium, of which Dr. Kashani is one of the principal investigators.

**Machine-Learning Applied to Neuroimaging Data Can Predict Brain Biological Age and Acceleration of Aging in Early Alzheimer’s Disease**  
This proposed research seeks to predict physiological brain age for individuals in healthy condition by leveraging deep learning-based modeling with brain image datasets. This project expands the model to predict how abnormality expands incrementally to different brain areas as mild cognitive impairment and AD develop, as a way to estimate the ‘survival’ probability explaining the remaining days in healthy status prior to the onset of MCI or AD. Ultimately this could lead to disease-specific risk scoring as a clinical tool to be used in routine patient care.

**Validation of a Biomarker that Could Identify a Subset of Frontotemporal Dementia and Alzheimer’s Disease Patients**  
Currently the medical field lacks reliable biomarkers to identify a subset of frontotemporal dementia (FTD) and Alzheimer’s disease patients with a particular type of pathology in the brain, accumulation of aggregated TAR DNA binding protein (TDP-43). The production of a new molecule, truncated stathmin 2, arising from TDP-43 aggregation, may be a way to indirectly assess TDP-43 pathology. We propose to develop tools to determine if there is an increased amount of truncated stathmin 2 in spinal fluid from AD and FTD patients compared to controls. These findings have the potential to help separate patients who would benefit from particular therapies in upcoming clinical trials.

**A New Imaging Method to Measure White Matter Damage and Inflammation in Alzheimer's Disease**

A PET-MRI method has been commonly used to identify tumors or strokes in patients with other diseases. These researchers adapt this method to measure the brain’s injury and immune response in patients who have Alzheimer’s disease, and to get a sense of the problems developing in their brain before memory problems occur.

[www.brightfocus.org/grant/A2017330S](http://www.brightfocus.org/grant/A2017330S)
As a neurodegenerative disease, Alzheimer’s is known for damaging neurons, which are the nerve cells of the brain. And in order for neurons to survive and function properly, they depend on oxygen and glucose carried through the brain’s blood vessels, or vascular system. Their needs are great because the brain consumes more energy than any other human organ, up to 20 percent of the body’s total supply. The brain relies heavily on an intricately laced system of arteries, veins and capillaries that, in adult brains, stretches an estimated 100 miles in length. For protection, the brain’s circulatory system is sealed off from that of the rest of the body by a special blood-brain barrier that helps prevent bacteria, viruses, and other toxic substances from entering. Together, the brain’s circulatory system and protective barrier are important to Alzheimer’s research because they are key to keeping neurons healthy.

**Prenatal Inflammation Programs Alzheimer’s Disease Risk Later in Life**

Recent animal model studies suggest a causal link between inflammation during embryonic development and risk of AD-like neuropathology later in life. In light of recent research demonstrating that blood-brain barrier breakdown in the adult brain is a core cause of AD, the hypothesis is that inflammation-mediated disruption of blood-placenta and blood-brain barriers are key factors in the developmental origins of AD.

**The Role of Chemical Messenger Signaling in Removing Alzheimer’s Pathology from the Brain**

The contribution of cerebral amyloid (Abeta) angiopathy (CAA) and cerebrovascular pathology to the progression of Alzheimer’s disease (AD) has received renewed interest in the field. This proposal expounds upon compelling preliminary data to test that degeneration of the locus coeruleus (LC) and cholinergic basal forebrain (CBF) projection systems contribute to cognitive impairment through their damaging effects on intramural peri-arterial drainage (IPAD) of Abeta contributing to AD/CAA. If successful, this proposal will advance the clinical rationale for targeting LC/CBF-mediated IPAD as a disease modifying strategy.

Investigating How Genetic Risk Contributes to Cerebrovascular Damage in Alzheimer’s and Dementia  

Historically, beta-amyloid plaques and tau tangles have been the focus of Alzheimer’s disease research. However, there is increasing evidence that brain vascular health is a critical component in the progression of the disease. A variant in the MTHFR gene has been linked to both vascular disease and Alzheimer’s in humans, but until now, no animal model represented this risk factor. Here, we have created a novel mouse model to study how MTHFR deficiency affects brain vascular health with age.

Why Is Brain Glucose Uptake Reduced in Alzheimer’s Disease?  
Blood vessels in the brain are surrounded by cells that contain a very large amount of a protein called aquaporin-4. In Alzheimer’s disease, the amount of aquaporin-4 around vessels is reduced. This project will test if this is causing the cells to swell around the vessels and block sugar from getting into the brain.

Studying Vascular Dysfunction of Cerebral Perforating Arteries in the Pathogenesis of VCID/AD  
By sharing common vascular risk factors, there is an increasing prevalence of Alzheimer’s disease and vascular cognitive impairment/dementia (VCID) with age. Small vessel disease (SVD) induced by the dysfunction of cerebral perforating arteries is one of the frequent vascular pathologies in the aging brain and VCID. The state-of-the-art 7T MRI with increased intrinsic signal to noise ratio (SNR) allows us to image the cerebral perforating arteries directly. In this study, we will optimize two high-resolution MRI techniques at 7T to quantitatively characterize the structure and flow function of cerebral perforating arteries, and study the role of dysfunction of cerebral perforating arteries in the pathogenesis of VCID/AD.

Understanding the Vascular Link Between Traumatic Brain Injury and Alzheimer’s Disease  
Traumatic brain injury (TBI) is a leading cause of injury deaths and disabilities in the United States and the most robust environmental risk factor for AD. Vascular impairment is also a hallmark of the pathological events after TBI, including local edema, blood-flow reduction and breakdown of blood-brain barrier, which may significantly increase Alzheimer’s risk. This project investigates the link between cerebrovascular impairment induced by TBI and its impact on the susceptibility to AD in animal models.  
www.brightfocus.org/grant/A2019218S
The human brain has an estimated 100 billion neurons; thankfully, quite a few to spare. Extending from each of them is a long fiber, known as an “axon,” which can run several feet. Each axon forms a connection, known as a “synapse,” with another neuron, creating a circuit over which brain signals travel. In Alzheimer’s disease (AD), individual neurons die and do not regenerate; yet some brains are resilient and will remodel themselves to meet new communications demands. If a circuit is too damaged to connect by the most direct route, signaling will sometimes take detours, known as indirect neural pathways. It’s not until the communications network completely breaks down that classic AD symptoms—things like forgetting loved ones, or becoming lost in familiar places—begin to occur. Scientists are studying the brain’s many cells and circuits, looking for ways to preserve communications for as long as possible after the onset of AD.

Above: From a live animal model, mitochondrial activity (green) in immune cells called astrocytes helps researchers determine whether changes in cell energy processing contribute to Alzheimer’s disease. (Courtesy of Maria Calvo-Rodriguez, PhD, Massachusetts General Hospital)

**Treating Memory Loss in Alzheimer’s Disease by Strengthening Synapses**

The insertion or removal of neurotransmitter receptors at synapses (connections between neurons) can promote learning, or forgetting, respectively. We recently discovered that a specific molecule called synaptotagmin-3 removes neurotransmitter receptors from synapses to promote forgetting. Mice missing synaptotagmin-3 have better memory than normal mice. This project will test whether removing or interfering with the function of this molecule in mice with Alzheimer’s disease will improve their memory.

Investigating Coordinated Removal of Old and Synthesis of New Materials in Neurons and How These Processes Are Disrupted in Frontotemporal Dementia  
Similar to how grocery stores maintain a full shelf of milk cartons by continually selling milk and obtaining new cartons, cells must balance the removal of old and synthesis of new materials. In neurons, insufficient removal of materials or defects in synthesis lead to loss of neuronal function, accumulation of toxic aggregates, and ultimately neuron death, contributing to the pathogenesis of neurodegenerative diseases such as frontotemporal dementia (FTD). This proposal examines how the distinct processes of removal and synthesis are interrelated. Imaging will be used to determine their physical and temporal relationship; drugs to block removal and determine the effects on synthesis; and neurons created from human cells to best determine the extent to which these processes occur during FTD.

Reprogramming of Skin Cells from Alzheimer Patients into Brain Neurons to Understand and Fight Cellular Memory Loss on the Molecular Level

Everybody ages, and unfortunately, this banal fact represents a huge health threat for us, because old age is the major risk factor for many human diseases, with Alzheimer’s disease leading the way. Our laboratory has recently found a way to reprogram cultured skin cells from Alzheimer patients directly into brain neurons, which are unique for each patient and also biologically ‘remember’ how old the patient was. In this project we aim to better understand this connection and try to find ways to give Alzheimer neurons their own memory back.

A Human Brain-in-a-Dish Model to Investigate Central Factors Required for the Formation of Alzheimer’s Disease Pathology

We currently do not understand well why the brains of Alzheimer patients contain aggregates of proteins and how these aggregates relate to the death of millions of nerve cells over time. To better understand the formation of plaques and tangles, we would like to investigate the building blocks that are required for the formation of Alzheimer’s disease (AD). For this purpose, we will turn human stem cells into nerve cells and other cell types found in the human brain, grow them together in a dish to assemble artificial human brain tissue, and introduce alterations in genes and cellular physiology that are typical for patients with inherited forms of AD. We will investigate if these models display Alzheimer pathology in a dish, and then modify the composition of cell types or the function of cells and their genes to learn which factors cause protein aggregation or nerve cell death in AD.

**Using Astrocyte Factors to Prevent Synaptic Alterations in Alzheimer’s Disease**

The brain is the center of command of our bodies, controlling our motion, our behavior and our feelings. Its main components, the neurons, process information by making specialized connections (synapses) between them, assisted by other important types of cells: the astrocytes. Alzheimer’s disease (AD) is associated with alterations in these connections. In this project I aim to restore the correct function of astrocytes, to rescue synaptic defects, in mouse models affected by AD and make a step further towards the cure of this devastating disorder.

Finding New Drugs and Treatments for Alzheimer’s Disease

Years of innovative and dedicated research have paid off with the discovery of numerous factors contributing to Alzheimer’s disease (AD) pathology. These discoveries have produced a bounty of “druggable targets,” and with a disease as complex as this one, it’s very helpful to find multiple points where it may be possible to slow or halt its progress. Unfortunately, only a handful of potential disease-modifying treatments has ever made it to the point of being tested in clinical trials. While many have not met their primary endpoints and been discontinued, many treatments are still being developed today. Support is needed for the type of high-risk, high-reward early research where discoveries in basic science may lead to the development of molecules and compounds aimed at reducing toxic protein buildup in AD, improving clearance of toxic particles, and delivering treatments to brain areas. The contributions gained from these exploratory projects at early stages are essential to get the next generation of drugs and therapies to patients.

**Washing Alzheimer’s Disease Off the Brain**
Alzheimer’s disease (AD) is the most common cause of dementia in the aging population, yet there is no cure to stop the progression of the disease. We propose to study a protective mechanism that drains potentially harmful toxins associated with the development of AD, such as beta-amyloid and tau proteins, outside the brain, and that has been recently characterized in animal models. We will use data from two large international studies of AD to investigate this mechanism in subjects at high risk for developing dementia associated with the disease. In investigating this mechanism for the first time in humans, our study could set the ground for future development and testing of therapeutic approaches to prevent the development of Alzheimer’s dementia.

**Protecting Brain Cells From Death Using Lipid Metabolic Drugs as a New Treatment for Alzheimer’s Disease**

There is still no cure for Alzheimer’s disease (AD), therefore, a major challenge for researchers in the field is to develop new therapies that prevent or delay onset of this disease. During the AD process brain cells, including neurons, are under attack by high levels of the lipid ceramide. The consequence of this elevation is that neurons are not able to produce enough energy and are more easily programmed to die. Hence, in this research proposal, we propose to reduce ceramide levels in the brain to protect neurons from dying as a new therapy for AD.

**Improving Cognitive Function in AD Therapy Using a Combinatorial Approach of Reducing Disease Progression and Increasing Memory**

Amyloid beta (Aβ) is the main component of amyloid plaques found in the brains of Alzheimer patients. Production of Aβ is nearly stopped by inhibiting BACE1 enzyme. Therefore, BACE1 inhibitors are used to reduce Aβ production and amyloid deposition. But their use can lead to many side effects that impact learning and storage of memory. Therefore, it is critical to develop new therapeutic strategies. We propose to use BACE1 inhibitor drugs in combination with mGluR activator drugs. This combination therapy will stop the disease progression and help in memory retention at the same time. We will test our strategy in mice in the current study. Positive results from this study could lead to treatments providing a better quality of life for Alzheimer’s patients.

The Impact of the Exercise Hormone Irisin on Astrocytes in Alzheimer’s Disease

Exercise reduces the risk of developing Alzheimer’s disease (AD) by up to 50 percent and protects against AD by modulating the inflammation which is heavily dependent on brain immune cells: astrocytes. Irisin is a novel exercise-induced hormone that has been identified to play a role in beneficial aspects of exercise. This work aims to understand the functional role of the exercise-hormone irisin in AD pathogenesis, and the underlying molecular mechanism of the neuroprotective effects of irisin in AD by regulating astrocytes. The data obtained in this proposal will advance our knowledge of irisin and astrocytes in AD, and ultimately be directed toward novel therapeutic designs that mimic the beneficial effects of exercise.

Understanding Alzheimer’s Disease to Avoid Side Effects of Drugs

Pharmaceutical companies have developed a drug, called BACE inhibitor, that has the potential to prevent and cure Alzheimer’s disease (AD). However, it is still uncertain whether this drug is safe for AD patients. Prior research suggests that this medicine could cause worsen side effects in people born with Down syndrome or carrying a specific genetic mutation causing AD. The goal of this project is to better understand AD caused by genetic risk factors, and ultimately find a safe drug treatment for AD patients.

Alleviating Alzheimer’s Disease with Novel Therapeutic Agents that Can Precisely Block the Production of Reactive Oxygen

Aging and neurodegenerative disease are associated with the accumulation of free radicals (also called oxidative stress) in the brain and other organs. Oxidative stress can damage cells and organs, promote disease, and impair brain function. We recently discovered small molecules that can block specific causes of oxidative stress without affecting normal cell functions. This research project will test whether these small molecules have therapeutic benefits in experimental models of dementia.

**Deciphering the Alzheimer’s Disease Glyco-code**

Alzheimer’s disease (AD) is a leading cause of dementia, involving cognitive decline, loss of independence and behavioral issues. Identifying the biomolecular deregulation associated with AD is crucial to decode the underpinning disease mechanisms, to discover new biomarkers, and to improve treatment strategies. This project will utilize an analytical workflow, allowing the exploration of the structure and biology of proteins and glycans in AD from patient tissue specimens. Outcomes of this project will benefit AD patients by generating the fundamental, previously unattainable, glycobiological knowledge required to improve the diagnosis and treatment of AD.

**Role of Platelet-derived Factors in Ameliorating Alzheimer’s Disease Pathology**

Aging alters the adult brain in ways that lead to impaired learning and memory, and an increased risk for Alzheimer’s disease (AD). A growing body of work indicate that factors in young blood have the potential to reverse age-related impairments in the brain in animal models of aging and AD. The proposed study will determine the therapeutic potential of young platelets, and platelet-derived circulating factors, to reverse neurodegenerative phenotypes in a mouse model of AD, and elucidate their downstream mechanisms of action. The results will have significant translational potential, identifying a blood-based therapeutic intervention to restore functions underlying AD-related cognitive impairments and broadly counter dementia-related neurodegenerative diseases.

Genomics:
DNA Blueprint for Alzheimer’s

Genes are the “master blueprint” that instructs our cells to make unique proteins which in turn build, operate, and repair human tissue. Humans have an estimated 24,000 genes along our 23 matched pairs of chromosomes (46 in all), and “genomics” refers to the field that studies all of them at once. Even slight changes in a gene on one or both chromosomes can produce a protein that functions abnormally, possibly causing or increasing/decreasing the risk of a disease such as Alzheimer’s. However, only one type of Alzheimer’s disease (AD)—early-onset forms, representing less than 10 percent—can be traced consistently to changes, or mutations, in identified genes. The remaining 90 percent—late-onset AD—is associated with small genetic irregularities occurring throughout the genome. Using powerful and fast new technologies, researchers working in genomics look for variations, patterns, and interactions among all genes in hundreds of thousands of people. So far, several dozen “regions of interest” have been identified, only it gets complicated because gene signaling can be turned “on” or “off” by additional factors, such as environment and lifestyle. Thanks to genomics, all this is being sorted out, and ultimately will help provide answers to basic questions, such as: What causes AD to start? How do genes interact with environment to raise or lower Alzheimer’s risk? Who is most at risk and apt to benefit from new treatments? What’s most likely to work in any given individual (“personalized medicine”)?

Gene Changes in Individual Cells Assessed Across the Progression of Alzheimer’s Disease

Alzheimer’s disease (AD) and other neurodegenerative diseases involve a loss of brain function and brain cells over time and eventually cause death, affecting one third of people over the age of 85. Recent research has found that brain cells build up new mutations in the DNA (known as somatic mutations) as we get older, which appears to harm the brain cells. This proposal will test the hypothesis that somatic mutations contribute in important ways to the pathologic progression of AD, and are related to other kinds of disease damage in brain cells, including oxidative stress.

A New Method That Uses the 3D Structure of the Human Genome to Identify the Genetic Basis of Alzheimer’s Disease  

Treatment options for Alzheimer’s disease have been elusive, in large part because the genetic causes of this disease are still largely unknown. The aim of this project is to integrate existing data with a novel experimental approach to identify genes that are linked to the development of Alzheimer’s disease. For that we will use modern genomic and gene editing techniques in a novel immune brain cell model generated from stem cells. Our work will break down existing barriers by using innovative techniques to speed the identification and characterization of unknown genes responsible for this disease. This will establish basic knowledge that the scientific community requires to develop new diagnostic and therapeutic approaches to detect and treat Alzheimer’s.

Using Population Sequence Differences to Identify a DNA Change that Reduces the Risk of ApoE for Developing Alzheimer’s Disease  

Carriers of ApoE4 with African ancestry have a lower risk for AD than carriers of European ancestry. These researchers have isolated the genetic region that protects African ApoE4 carriers and will use this study to identify DNA changes among the populations that can be tested in biological models.

www.brightfocus.org/grant/A2018425S
One theory about Alzheimer’s disease (AD) is that it may be triggered, in part, by a breakdown in the brain’s immune system. Normally our brain has ways of clearing damaged cells and unwanted particles in its midst and disposing them into the bloodstream—which can be thought of as “taking out the garbage.” However, a chronic rise in unwanted debris, including toxic amyloid beta (A\(\beta\)) and tau proteins, can short-circuit that process and lead to chronic inflammation and cell damage.

Grantees are looking at what causes the immune response to become unbalanced and whether there are ways to help the brain’s cells and immune system do a better job of fighting Alzheimer’s.

Above: This close-up of brain cells from an animal model shows lipid droplets (red) accumulating in immune cells called microglia (green) that are surrounding amyloid plaques (blue). (Courtesy of Christel Claes, PhD, University of California, Irvine)

**Examining How the TREM2 R47H Mutation Affects Microglial Lipid Content and the Interactions Between Human Microglia and AD pathology Within the Brain**

Our recent studies show that when we transplant healthy human stem cell-derived microglia carrying a normal version of the gene, TREM2, into the brain of Alzheimer mice that develop amyloid plaques (a main characteristic of this disease), human microglia near the plaques show similarities to peripheral ‘foam cells’, which are immune cells filled with lipids and linked with another disease called atherosclerosis. As TREM2 is a lipid-sensor expressed by microglia, we now want to study the lipid content and the reaction of human microglia that carry the TREM2 R47H mutation to amyloid plaques in this specialized mouse model, to greatly improve our understanding of how this mutation can increase Alzheimer’s risk, which will in turn allow scientists to find treatments that increase the functionality of microglia to protect our brain from the damage caused by these amyloid plaques.

Is Hexokinase 2 a Molecular Link Between TREM2 Signaling and Microglial Activity in Alzheimer Disease?
Alzheimer’s disease is a neurodegenerative disorder that induces the activation of the brain immune cells, the microglia. Mutations in a gene expressed only in microglia, TREM2, increase the risk of late-onset Alzheimer’s. However, the molecular mechanisms involved in TREM2 function are not fully understood. In this study, we want to evaluate if TREM2 can induce metabolic changes in the microglia through the regulation of hexokinase 2 an important enzyme of the metabolism of glucose.

**Evaluating the Role of Immune Cells in the Brain and a Related Protein, TREM2, on Alzheimer’s Disease Pathology**

Aggregation of the tau protein in the brain is a hallmark of Alzheimer’s disease (AD), and the propagation of aggregated tau protein is strongly associated with neurodegeneration and dementia. In addition, brain immune cells, known as microglia, play a crucial role in AD and the propagation of tau pathology in the brain. Indeed, mutations in TREM2, a protein found on microglia, are one of the strongest genetic risk factors for AD. Therefore, we will investigate if decreasing microglia or TREM2 levels in the brain can modulate tau propagation.

International Brain Bank for Down Syndrome-Related Alzheimer’s Disease

The focus of this special project is to develop a strong collaborative network between six different research groups, with the long-term goal to determine the neurobiological mechanisms underlying the onset of Alzheimer’s disease-type dementia in Down syndrome.

www.brightfocus.org/grant/CA2018010
As a protein associated with Alzheimer’s disease (AD), tau is abundant inside neurons, where its fibrous shape lends stability to tubes that transport nutrition and waste in and out. However, in AD, tau goes through molecular changes that cause it to misshape and collect in messy tangles. Unlike Aβ plaques, which can form years and even decades before AD symptoms occur, tau tangles typically are a sign that AD is rapidly getting worse.

Current theories hold that Aβ and tau interact in ways to make that happen, and scientists are investigating how tau may be involved in spreading AD throughout the brain.

**Slowing Alzheimer’s Disease by Enhancing Cellular Garbage Disposal**  
This project tests the effectiveness in animal models of a drug that stimulates the brain’s own “garbage disposal units” (the proteasome) to remove the toxic proteins that form clumps in the brain and cause the memory loss.

**Improving Detection of the Earliest Signs of Alzheimer’s Disease to Help Prevent Memory Loss**  
The project aims to use brain imaging (PET scans) in healthy older adults to visualize the earliest signs of amyloid plaques, and determine how the buildup of these amyloid plaques contributes to the appearance of tau tangles inside brain cells and subtle changes in memory and thinking. This research will provide urgently needed information about the early stages of development of Alzheimer’s disease (AD), and help the next generation of prevention trials target individuals who are at an optimal point in the development of AD for successful intervention.

**Blood Test to Identify and Distinguish Alzheimer’s from Other Neurodegenerative Diseases**  
There are currently no blood tests to determine if a person has Alzheimer’s disease (AD). It can be difficult to determine whether a person with dementia has AD, a different neurodegenerative disease, or both simultaneously. The research team has created a new antibody, named GT-38, that detects a form of tau protein present in AD but not the other neurodegenerative diseases. GT-38 will be used to develop a test for blood or cerebral spinal fluid to distinguish AD from other neurodegenerative diseases.

Detecting the Shape Changing Protein Tau in Alzheimer’s Disease  
The tau protein normally adopts a “good” shape and with age converts into a “bad” shape. This project aims to understand how tau changes into the “bad” shape to help understand how to detect this in patients and develop therapies to prevent it.

Twisting Away Toxic Proteins in Alzheimer’s Disease  
Tau aggregation is a major pathogenic factor in Alzheimer’s disease. Our studies have identified a family of proteins that alter tau aggregation, including one member of this family which can disaggregate tau aggregates into smaller non-toxic entities. The goal of this proposal is to elucidate the mechanisms of this disaggregation towards the ultimate goal of designing therapeutic strategies that mimic this activity. These studies will identify the properties and number of members of this protein family that present this activity while simultaneously examining the properties of tau that facilitate toxic aggregation and accumulation.

**Determine Whether PIWIL and piRNAs are Dysregulated in Tau Transgenic Mice and Human Neurodegenerative Tauopathies**  
Recently, research with fruit flies identified a new mechanism to address tau toxicity and jumping genes through PIWI protein and PIWI-interacting RNAs (piRNAs). To investigate if this mechanism is conserved in vertebrate tauopathy, this project will whether this same mechanism is intact in mouse models of AD so that model can be used to whether piRNAs identified in AD are directly bound to PIWI-like proteins and are relevant to brain cell death in AD.

**Understanding the Role of Lysosome in Brain Function and Alzheimer’s Disease**  
Accumulation of tau aggregates influences brain health and cognition in Alzheimer’s patients. These aggregates are degraded by an intracellular organelle called the lysosome. TFEB plays a critical role in regulating lysosomal function and its clearance ability. Our proposal investigates how TFEB works with the goal to identify ways to harness the lysosomal function to promote brain health and combat age-associated neurodegenerative diseases.

**A Novel Way to Expand Human-Derived Pathogenic Tau Seeds in a Cell Free System**  
Tau aggregates (tauopathy seeds) enriched from the postmortem brains Alzheimer’s disease (AD) patients exhibit specific biological activity of inducing normal tau into misfolded pathological tau. But the quantity and quality of the tauopathy seeds are very much limited. In the study, we will explore the seeding mechanism of the human tau seeds using in vitro reactions for a better understanding of the pathogenesis of AD and other tauopathies. Moreover, we want to amplify tauopathy seeds in vitro by making use of the self-propagating features of them and promote future studies of tau pathology transmission.

“Translational” research refers to the effort to take basic science knowledge from the laboratory or research setting into the “real world” in the form of potential treatments or cures. In this context, it refers to the act of literally “translating” science into useful ways of diagnosing, treating, and managing Alzheimer’s disease (AD). These innovations can take many different forms, such as using smartphone-based testing to monitor cognitive status in AD, to finding ways for individuals with AD to get better sleep and exercise, since scientists have associated these lifestyle activities with brain health and possible protective benefits. Another very important undertaking is that of testing new drugs and interventions in humans once they are deemed safe, and this is done through clinical trials and another studies which rely on volunteers who are willing to participate. These activities will help speed drugs, treatments, and critical knowledge from “bench to bedside” and put them in the hands of people living with AD today or facing the risk of it in the future.

**Gene Correction as a Therapy for Frontotemporal Dementia (FTD) and Amyotrophic Lateral Sclerosis (ALS) caused by the C9orf72 Mutation**

Frontotemporal dementia (FTD) and amyotrophic lateral sclerosis (ALS) are two fatal and incurable neurodegenerative diseases linked by a shared genetic cause – a heterozygous hexanucleotide (GGGGCC) repeat expansion in a single allele of the C9orf72 gene. The goal of this work is to develop novel CRISPR based therapeutic gene editing technologies and test whether gene editing can reverse the cellular pathology caused by this repeat expansion in patient derived cells. The results of these studies will advance our use of CRISPR technologies for therapeutic editing in FTD/ALS, inform our understanding of the regulation of C9orf72 gene, and will be applicable to many other repeat expansion and single gene disorders.

**Testing New Markers of Brain Function that May Be Sensitive to Early Signs of Alzheimer’s Disease in Older Adults Who Still Have Normal Cognition**

The goal of this study is to develop tests that can detect changes in the activity of the brain at the earliest stage of Alzheimer’s disease (AD), before patients start showing symptoms, which is known as “preclinical Alzheimer’s disease.” We will recruit healthy older adults with normal cognition and use a new blood test that can detect the proteins—called amyloid—that are linked to AD. We will collect a range of measures of the activity of the brain and relate the measures to the amount of amyloid. Knowing more about what changes are occurring in the brain in preclinical AD and how to measure them will help researchers develop new therapies to change the course of the disease to delay or prevent dementia.

Improving Recruitment to Prodromal Alzheimer’s Disease Clinical Trials

Most Alzheimer’s clinical trials now enroll patients with mild cognitive impairment, which in many cases may be an early form of Alzheimer’s disease. This project will identify the challenges to enrolling these patients in clinical trials and develop methods to improve recruitment to these critical studies.

www.brightfocus.org/grant/A2018405S

Magnetic Stimulation to Treat Alzheimer’s Disease

The primary aim of this project is to investigate a non-invasive brain stimulation, repetitive transcranial magnetic stimulation (rTMS), on memory skills in patients with mild Alzheimer’s disease (AD). rTMS is considered a safe, well tolerated and relatively cheap treatment. The appealing idea of our intervention is to improve memory by directly modulating the activity of precuneus, a key area of the brain linked to memory impairment. This project will provide a valid treatment to slow the worsening of symptoms and improve quality of life for those with AD and their caregivers.

Identifying Disease Mechanisms in Neurodegeneration Using Electrophysiology

Agitation and aggression affect the majority of patients with Alzheimer’s disease. Medications used to treat these symptoms are associated with many side effects. This project will use magnetic brain stimulation and electroencephalography to understand the mechanisms of agitation and use a non-invasive brain stimulation technique called transcranial direct current stimulation (tDCS) to treat it.

www.brightfocus.org/grant/A2018667S
Cure for Alzheimer’s disease is still lacking. It is important to identify the risk factors for the disease and its multiple impacts on body functions in order to prevent or slow down the progression of the disease and treat related symptoms. Using novel non-invasive assessment of circadian regulation and autonomic function by wearable technology, this project is designed to determine whether changes in these two important physiological functions can predict the development and progression of Alzheimer’s disease (AD) and cognitive decline in the elderly people at early, preclinical stages. This project may potentially provide new intervention targets in future clinical studies of AD, and can lay the groundwork for the design of novel unobtrusive, cost-efficient tools for long-term monitoring of cognitive impairment or risk for AD.

www.brightfocus.org/grant/A2020886S

The goal of this project is to increase the knowledge of the effects of a physical activity program on dementia prevention in African-American adults.

www.brightfocus.org/grant/A2017547S

This study will explore the relationship between sleep, memory, thinking, and markers of brain health by investigating whether improved sleep causes better memory and thinking, slows protein build up in the brain, and slows the shrinking of the brain.

Dissemination Of MIND At Home Dementia Care Model To Drive Health Care Transformation And Greater Value

Evidence-based dementia care model that assesses and addresses a broad range care needs that place elders living at home with dementia and their family members at risk for a host of undesirable outcomes including hospitalizations, unwanted long term care placement, poor quality of life, health disparities, caregiver burnout. Thie grant partners with University of Maryland Baltimore County, Jade Gong & Associates LLC, and Johns Hopkins Home Care Group, with the support of Maryland Primary Care Program, Maryland Medicaid, and Johns Hopkins Alliance for Patients to advance the dissemination of the MIND at Home model into real world practice. Grant activities will include a cost benefit analysis to understand the program’s value to payers and providers; engagement of primary care providers and health plans participating in the Maryland Primary Care Program (MDPCP) to understand provider needs and potential interest in the MIND at Home Program; and finally refinement of the MIND at Home program delivery process and financing model based on these newly captured data. Results from this work will inform the dissemination of the MIND at Home program into MDPCP and learnings will likely generalize to broader, national health care cost reduction initiatives in the future.
