

# Macular Degeneration Research Current Grantees

Advanced forms of age-related macular degeneration (AMD) are a leading cause of vision loss and irreversible blindness in Americans age 60 years and older, as well as throughout the world. As many as 11 million Americans have some form of macular degeneration, including both early and later stages of the wet and dry forms. This number is expected to double by 2050. Since treatments are limited or nonexistent for several AMD stages and types, much more work is needed to develop effective treatments and cures.

With the support of our donors, Macular Degeneration Research (MDR), which began in 1999, has awarded more than \$21.5 million to fund research projects on the cause, potential prevention, and treatment of this disease. The standard MDR grant is \$160,000 over two years. In the past three years alone, MDR has funded 55 research projects totaling \$7.5 million.

MDR is currently supporting 40 research projects, which are described in this yearbook.

## IN THE U.S.A.

Roughly **2 million people**  
have advanced AMD.

Incidence is expected to  
**double** by 2050.

## Understanding Early AMD

As the eyes age, there's a breakdown in its ability to get rid of cholesterol, which collects in drusen and triggers an immune response. That may be one of the tipping points leading to early AMD, followed by inflammation and eventual cell death. A stiffening of blood vessels, which happens in the eye as it does in the body, may contribute further. AMD is a disease linked to not just one, but many, causes. Foremost are changes in the eye that happen with age—the strongest risk factor. MDR is funding scientific exploration that will expand our understanding of AMD and open new and earlier avenues for treatment.

## RPE and Drusen Formation

It's widely thought that macular degeneration, and its most common form AMD, begins with activation of immune cells in the retinal pigment epithelium (RPE), a pigmented layer of cells next to the retina. The RPE's role is to protect and nourish the nerve cells by transporting molecules in and out. As one of the starting points of AMD, the RPE is sensitive to damage brought on by age, oxidative stress, and other factors. That may trigger chronic inflammation, which confuses RPE cells and impairs their ability to clear away debris ("autophagy"). Small fatty particles, known as exosomes, are released by RPE cells and may be involved in drusen formation, yellow deposits under the retina that are made up of fatty protein. When spotted on an eye exam, drusen often are the first obvious sign of disease.

**Francesco Giorgianni, PhD** (7/1/2016 – 6/30/2018)

University of Tennessee Health Science Center

*Basic and Clinical Studies to Understand the Role of the CD5L/ AIM Protein in AMD*

*"The main objective of our research project is to reveal the cellular and molecular mechanisms involved in AMD by studying two key pathological events that characterize AMD: the accumulation of drusen deposits and the death of RPE cells."*

## **New Approaches to AMD Treatment**

What will be the next “gold standard” treatment for AMD? MDR is funding research into unique ways to protect the retinal pigment epithelium (RPE) and retina at earlier stages, before damage to sight has occurred. These include drugs that enhance immune functioning and improve the eye’s ability to clear lipids and other waste that might otherwise lead to inflammation. Researchers are also looking at ways to restore health to the aging eye by improving its metabolism, or efficiency at storing and using energy.

**Kip Connor, PhD** (7/1/2016 – 6/30/2018)

Schepens Eye Research Institute/Massachusetts Eye and Ear, Harvard  
*Lipid Regulators of AMD*

*“Our proposal has clear potential to lead to new therapeutic molecules, targets, and strategies for specifically inhibiting neovascular AMD, a leading cause of blindness in the elderly which, if left untreated, rapidly leads to substantial vision loss.”*

**Diana Pauly, PhD** (7/1/2015 – 6/30/2017)

University Hospital Regensburg, Germany

*Can Proteins Block Inflammation in the Eye and Ameliorate AMD-Pathology?*

*“For this research, we will generate an array of protein tools, designed such that some of them will eventually be developed into novel therapeutics for the inhibition of overactive inflammation in the human eye during AMD pathology.”*

[www.brightfocus.org/grant/M2015186](http://www.brightfocus.org/grant/M2015186)

## Drug Discovery & Development

There are currently no drugs to treat advanced forms of dry AMD, also called geographic atrophy (GA). And despite the success of drug injections for wet AMD, not all patients respond. New therapies are needed, and MDR-funded investigators are exploring new drugs and conducting early tests of their potential. These include new agents that work to block blood vessel growth in wet AMD, as well as compounds to treat dry AMD which, if successful, could be among the first drug treatments.

**Tim Corson, PhD** (7/1/2015 – 6/30/2017)

Indiana University School of Medicine

*New Drugs to Treat Abnormal Blood Vessel Growth in Wet AMD*

*“Starting with a new chemical that we developed that blocks blood vessel growth, we will design and produce related chemicals that are even more potent and selective for blood vessel cells over other cell types.”*

[www.brightfocus.org/grant/M2015301](http://www.brightfocus.org/grant/M2015301)

**Benjamin Kim, MD** (1/1/2016 – 6/30/2017)

University of Pennsylvania

*Therapeutic Evaluation of Alpha Lipoic Acid for GA*

*“Through a Phase II pilot clinical trial, we are testing alpha lipoic acid as a treatment for GA.”*

## Insights into Geographic Atrophy

Geographic atrophy (GA) is a type of AMD that's also called "dry" AMD because it lacks the fragile, leaky blood vessels seen in late-stage "wet" AMD. Instead, photoreceptors weaken and die ("atrophy"), resulting in dead zones and an expanding blind spot near the center of the visual field. There is no treatment for late-stage GA and MDR is funding projects aimed at finding better treatments and a cure. New imaging and analysis techniques will help us understand GA lesions and do a better job of tracking progression over time. Additional projects focus on genetics: conducting rapid analysis on the world's largest collection of AMD samples to pinpoint genes that interact in both dry and wet AMD, and experimenting with gene therapy.

**Paul Baird, PhD** (7/1/2016 – 6/30/2017)

Centre for Eye Research Australia, The University of Melbourne  
*Identifying Gene Pathways in Late-Stage AMD*

*"This project will look at how different regions of our genetic background interact with other genetic regions and lead to AMD."*

**Mikael Klingeborn, PhD** (7/1/2015 – 6/30/2017)

Duke Eye Center, Duke University

*The Role of Cell-Derived Lipid Vesicles in Early & Atrophic AMD*

*“Our research seeks to understand what causes the earliest stages of the dry form of AMD.”*

[www.brightfocus.org/grant/M2015221](http://www.brightfocus.org/grant/M2015221)

## **Rescue & Regeneration of Sight Damaged by AMD**

Eyesight is precious and irreplaceable. Unlike skin and other parts of the human body, the nerve cells of the eyes do not, for the most part, regrow or regenerate after damage has occurred. However, there is hope, and researchers are exploring whether it might be possible to “rescue” cells from early AMD damage using growth factors and other natural hormones that offer protection. In addition, work is moving forward to regenerate and reconnect the eye’s retinal cells, and to restore the underlying RPE that provides its nourishment and support. They are recreating parts of the eye using induced pluripotent stem cell (iPSC) technology (stem cells derived from living adult tissue), and cell growth is being studied in other members of the animal kingdom with the hope of gleaning information that will benefit human eyes.

**Derek van der Kooy, PhD** (7/1/2016 – 6/30/2018)

University of Toronto, Canada

*Biomaterial-based Stem Cell Therapies for Blinding Eye Disease*

*“We are focused on the goal of producing large quantities of cone photoreceptors for transplantation directly into the retina. Cones are the cells responsible for high-resolution/color vision and are lost in AMD.”*

[www.brightfocus.org/grant/M2016173](http://www.brightfocus.org/grant/M2016173)

**Petr Baronov, MD, PhD** (7/1/2016 – 6/30/2018)

Schepens Eye Research Institute/Massachusetts Eye and Ear, Harvard

*A New Approach to Rescuing Photoreceptors from Death through Activation of Endogenous Neuroprotective Mechanisms*

*“We aim to identify small molecules that can induce endogenous growth factors in the sensory part of the eye, the retina. The results of our studies should lead to the development of novel, accessible and effective molecular therapies for retinal degeneration and other neurodegenerative disorders.”*

[www.brightfocus.org/grant/M2016046](http://www.brightfocus.org/grant/M2016046)

**Behzad Gerami-Naini, PhD** (7/1/2014 – 6/30/2017)

Tufts University

*Using Cells from Teeth to Replace Damaged Cells in AMD*

*“Our work is focused on developing a novel cell therapy intervention to treat AMD by replacing diseased RPE cells with newly made replacement cells, generated from cells found in the dental pulp of extracted teeth and grown on a special silk surface.”*

[www.brightfocus.org/grant/M2014059](http://www.brightfocus.org/grant/M2014059)

**Jeffrey Gross, PhD** (7/1/2016 – 6/30/2018)

University of Pittsburgh

*Identification of Factors that Can Stimulate Regeneration of the RPE*

*“The goal of our work is to determine whether the human RPE can be stimulated to regenerate.”*

[www.brightfocus.org/grant/M2016067](http://www.brightfocus.org/grant/M2016067)

**Biju Thomas, PhD** (7/1/2016 – 6/30/2018)

Roski Eye Institute, University of Southern California

*Transplantation of iPS-RPE as a Polarized Monolayer*

*“We propose to treat such diseases by transplanting a polarized monolayer of retinal pigment epithelium (RPE) sheets derived from human induced pluripotent stem cells (iPS), which are stem cells that have been derived from adult human tissue.”*

[www.brightfocus.org/grant/M2016186](http://www.brightfocus.org/grant/M2016186)

**Sara Venters, PhD** (7/1/2014 – 6/30/2017)

University of California, San Francisco

*Investigating Central Neural Retina Development in a Vertebrate Model*

*“The central retina is specifically affected in several eye diseases, and discovering what makes it unique can help with treatment and future therapies for re-growing this portion of the eye. Our research goal is to identify the definitive origin and specific developmental mechanisms underlying the establishment of central neural retina cells.”*

[www.brightfocus.org/grant/M2014060](http://www.brightfocus.org/grant/M2014060)

## New Hope for Preventing AMD

One day we may be able to detect signs that AMD is developing and prevent it from damaging eyesight. Many different strategies are being explored. One early sign, there may be inflammatory factors in blood that could serve as preclinical biomarkers for AMD; also it may be possible to image inflammation at the cellular level to alleviate the early immune response. Another early sign of AMD is a slowdown in the retina's ability to recover from light exposure, and a simple test of the eye's response to light is being evaluated for predictive value. Knowledge of genetics is advancing to the point that it may be possible to replace or block gene signaling that triggers AMD. As yet another protective mechanism, researchers are looking at ways to increase stress resistance and promote survival and integrity of the retinal pigment epithelium (RPE) as it encounters oxidative stress from aging and other causes.

**Marie Burns, PhD** (7/1/2015 – 6/30/2017)

University of California, Davis

*Window to Health: New Ways to Detect the First Signs of Cell Sickness in the Eye*

*"One big-picture goal of our research is to identify cells in distress and to heal them before they die and before patients lose their sight."*
